# Presentation's Overview

- 1 Aduka-II: The Project
- 2 Aduka-II: The Prototype
- 3 Flatnened Device Tree - FDT
- 4 What is next?

# Aduka-II: The Project

- "Aduka" is a hexapod robot which can be remotely controlled;
- Aduka-II is the second (and current) version of this hexapod robot;
  - It all started in a research laboratory with a motivation to create an innovative project for embedded systems related to the educational field of robotics; it was Aduka-I.
- Since its very first version we went out of any "comfort zone";
  - FreeBSD was getting support on BBB;
  - There was no hexapod at that point running a BSD system;
  - Why not to try to build one?
- The project is being developed at the "Laboratório de Inovação Tecnológica (LIT/IFCE)- Fortaleza - Brazil;
- All material and financial support is also provided by LIT/IFCE.

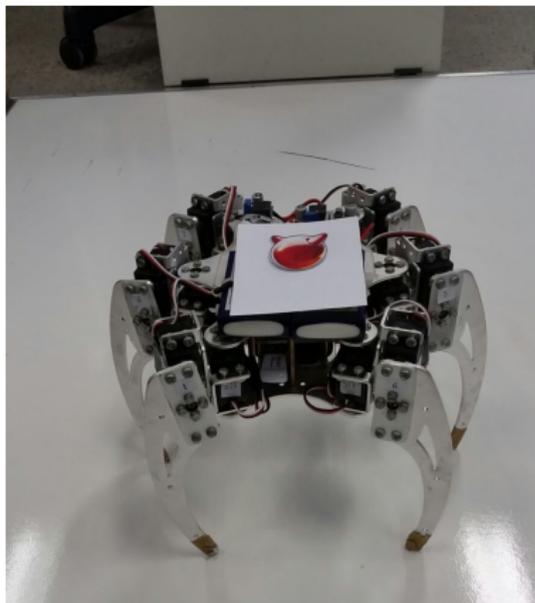

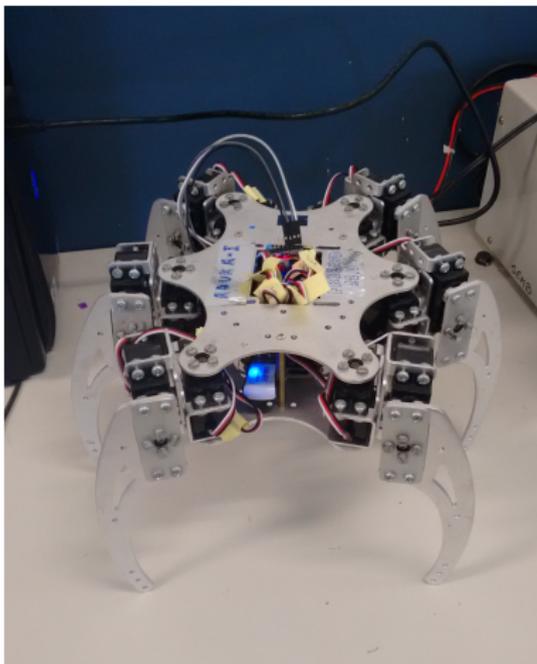

## So, what is exactly this talk about?

- The main idea of this talk is to show the possibilities of developing a remotely operated hexapod robot (Aduka-II, in this case) and its control system out of many researchers' comfort zone.

# Aduka-II: The Prototype

# System Description

- It is a bioinspired robot;
- It uses single boards to control robot movement;
- It is a ROR - Remote Operated Robot;
- It is powered by FreeBSD 11.0-CURRENT;
  - ... with mix of Python (2.7) and C;
- It provides a server/client application via WiFi (hostapd);
- It controls 12 servomotors via serial communication;
  - ... and here comes our 12 DOF;

# Hardware Platform

The Aduka II-robot makes the use of single boards, which together compound the hardware platform.

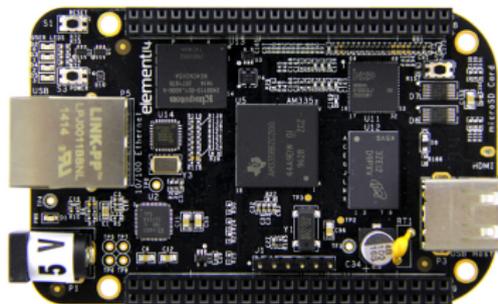

- BeagleBone black (Revision C);
- Servo Motors;
- PWM driver board;
- Batteries;
- Voltage regulators boards.

# BeagleBone Black

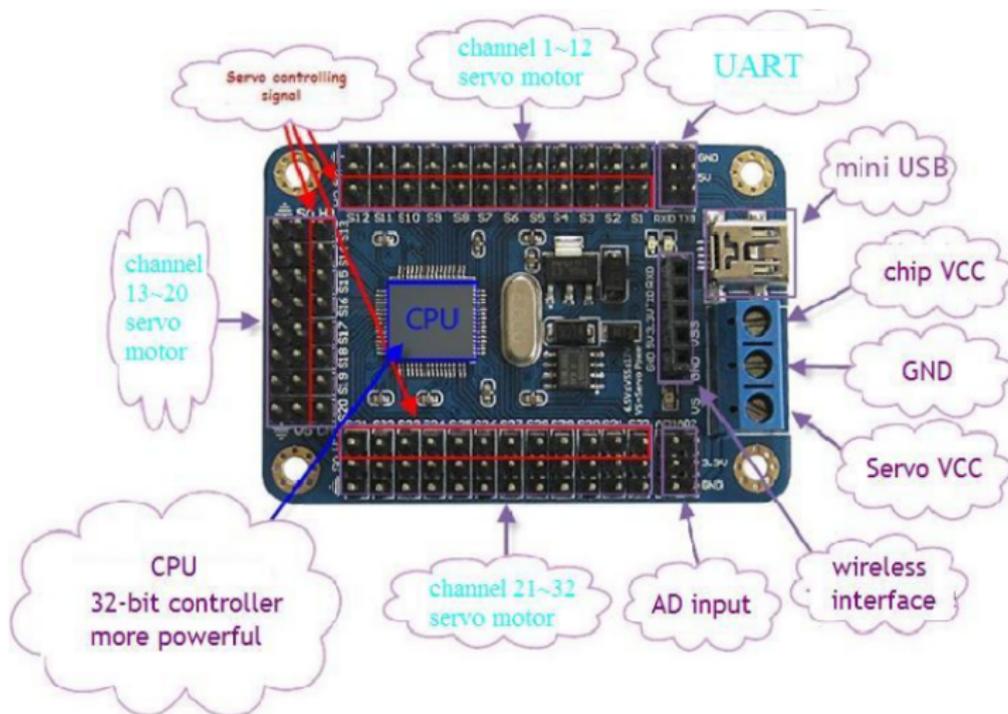

## Features:

- The BeagleBone Black is a System on Chip (SoC) board developed by Texas Instruments and is available on the market for embedded systems developers, enthusiasts or hobbyists;
- Wifi support and Serial Communication;
- Boot from a microSD card;
- Compact size, light weight and low power consumption;
- Aduka-II uses BBB revision C.

# Pulse Width Modulation(PWM) driver board

As BBB has only 4 PWM channels, we decided to use a dedicated board to generate the PWM for servo motors.

# Communication Protocol

The two boards communicate using serial 0 (tty0).

Format: # <ch> P <pw> ... # <ch> P <pw> T <time> \ n \ r

<ch> = Servo number, range 1~32 (decimal number)

<pw> = Pulse width (servo position), range: 500~2500. Unit: us (microseconds)

<time> = Time used to move to the position, effective for all servos.

\ n \ r = Binary number 0x0d, 0x0a (carriage return), the command terminator

# Servo Motors

Aduka-II has 12 servo motors, two per leg, that support and move the robot in different directions.

Servo motor Futaba S3003

# Power Source

DSN2596

To power up Aduka-II there are two batteries, one dedicated to servo motors and other dedicated to power the boards.

# Software Platform

The software platform consists of a FreeBSD system running simple custom coded Python scripts to control the 12 servomotors. It also gets the benefits of FreeBSD to serve a small WiFi network between the bot and the client controlling it.

# Why FreeBSD?

- FreeBSD is known and considered as one of the most robust and secure multi-user and multiplatform operating systems of modern computing;
- FreeBSD is developed by hundreds of high level and recognized engineers, including, but not limited to, BSc., MSc. and PhD. students and professors in various computer science (+engineering) fields;
- FreeBSD supports the largest academic and government backbones in the world;
- FreeBSD serves educational institutions, research, innovation and development foundations or companies around the globe;
- POSIX.1e, TCP/IP, f-root, DC/B3 EAL4, IPv6, ...

# FreeBSD on BBB: First Steps

The BeagleBone Black can boot from either the built-in eMMC or a micro-SD card. In this current scenario, Aduka-II still needs a FreeBSD system to be booted from micro-SD. The board was also shared with other researchers in the lab.

To start "Aduka":

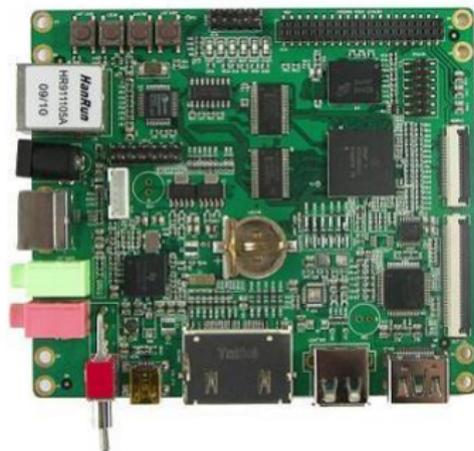

- A micro-SD card with an image of FreeBSD for armv6 must be inserted at the BBB;
- The "Boot Switch" button must be pressed and holded (it is the button on the top of the board near the micro-SD slot);
- Power it up, either via a 5v adapter or through a mini-USB cable.

The switch state is recorded by the power chip when power is first applied and will be kept until power is removed.

# Packages? Custom Kernel Images?

- Once upon a (sad) time ...
  - Gentoo Linux
  - DevKit8000; OMAP 3530, Cortex-A8
  - BeagleBSD

- Now ...
  - Crochet

- release.sh

# Packages? Custom Kernel Images?

- There wasn't an official repository for ARMv6 packages;
- Get in touch with custom images and packages for ARMv6 would support/help the FreeBSD project too
  - Problem reports (PR) were created; some to base and ports:
    - sys/boot/fdt/dts/arm/beaglebone-black.dts (r287419), #197609, #197332, ...
- Building "Aduka" should also be fun, right? ]=)

# Supervisory System for Aduka-I

- As soon as some packages were created and installed, an interface (Python) for controlling the robot just born.

```

Aduka-I
FreeBSD 11.0-CURRENT (ARMv6) #0 r288346
Tue Sep 29 11:13:56 BRT 2015
http://vps84.lit.ifce.edu.br/charlie

In order to support national characters for European languages in tools like
less without creating other nationalisation aspects, set the environment
variable LC_ALL to 'en_US.ISO8859-1'.

# Supervisory System for Aduka-II

- The new version of the interface to control the robot.

The screenshot shows a terminal window titled "Supervisory Screen Aduka-II" with a menu bar (File, Edit, View, Search, Terminal, Help) and a timestamp "Thu 06/09/2016 02:34:51". The main display area contains the following text:

```
Supervisory Screen Aduka-II                               Thu 06/09/2016 02:34:51

Battery Servo =

Battery boards =

Direction

Robot View
```

The "Robot View" is represented by a white rectangular box. At the bottom of the terminal, a green status bar displays the command prompt and execution details:

```
[0] 8:python2.7: 1:python2.7*
[1] 8:rcab- 1:rcab- 2:rcab-
```

On the right side of the green bar, there is a timestamp: "aduka-11" 02:34 09-Jun-16 and "aduka" 02:36 09-Jun-16.

# Locomotion matrices

# Flatnened Device Tree - FDT

## Benefits:

- Put outside the kernel the device definitions;
- Same kernel for multiple similar boards;
- Make it easier to enable/disable devices after a kernel build;
- To mux the pins for alternatives functions;
- To list all the devices and their properties.

To enable or redefine some I/O pins just edit the .dts clear text file and compile the .dts into a .dtb binary file with dtc.

# Demo

No live demo this time. It is too dangerous! Safety first ]=)

# What is next?

- Setting up magnetometer via i2c (position feedback);
- To include a camera for visual feedback (driver?);
- GPS;
  - Automated (moon)walking
- Battery status (ADC library).

# Thank you!

# Questions?
